I am attempting to build a daily digest, provided and disseminated by a custom engram.

ChatGPT said:

What do you mean by a “custom engram”—a custom GPT, an agent in a particular platform, or something else?

To build the daily digest, I also need to know:

- **Content:** What should it cover, and which sources should it use?
- **Delivery:** Who receives it, through which channel—email, Slack, or another destination?
- **Timing:** What time and timezone should it arrive?

A rough description is enough to start.

Here is my career progression prompt: I am a 32 year old transwoman, avid vegan cook blogger on instagram, otaku-cyberpunk2077 specific who only invests in media that maintains representative voice acting, that is attending University online and pays all bills online. This should be a self-contained, self-published .apk that features the option to integrate custom engrams and .gguf files for full data analytics and simulation.

ChatGPT said:

You’re describing a standalone Android app for your daily digest and career development, with your interests and values shaping its recommendations.

I'd turn your description into this working brief:

> Build a self-contained Android app, distributed directly as an APK, that produces a personalized daily digest and supports career planning. Tailor it to a 32-year-old trans woman studying online, creating vegan cooking content on Instagram, and interested in anime and Cyberpunk 2077. Respect her preference for media with representative voice casting.
> Support configurable "engrams"—personas with their own instructions, preferences, and optional memory—and importing local GGUF models. Define analytics around user-selected data and simulations around explicit scenarios, such as balancing coursework, content creation, and career goals. Clearly distinguish simulated outcomes from observed data.
> Keep personal data on-device by default. Make external data connections optional and explicitly configured. Provide digest scheduling, local notifications, and export options.

Two decisions will determine what we build:

1. **What career outcome should this support?** Growing your vegan creator business, finding work related to your degree, or exploring possible careers?
2. **What does "custom engram" mean in your setup?** An existing format or platform, or the configurable persona described above?

Also, what Android phone will run it? That will help set realistic limits for local model size and performance.

You said:

This supports any career that the user inputs. Custom engram is a character bio that works within the API or localized/offline .gguf to fully simulate an assistance based companion within autonomy, self-determination, and neural plasticity development.

ChatGPT said:

Understood. The app should support **any career the user enters**, while your personal profile serves as an optional example rather than a fixed target audience.

An **engram** is a portable character biography that shapes the companion's voice, values, interaction style, and boundaries. It works with either an API-hosted model or a compatible local GGUF model; the biography itself is separate from the model.

The app's core workflow becomes:

- **Set a direction:** Enter a career, current skills, constraints, and goals.
- **Configure a companion:** Import or create an engram, choose a model, and control what it remembers.
- **Receive a daily digest:** Review relevant developments, learning priorities, opportunities, and practical next steps.
- **Explore scenarios:** Practice interviews, rehearse conversations, and compare career paths using clearly labeled assumptions.
- **Build skills:** Use reflection, spaced practice, and progressively harder exercises. These support learning without claiming to measure or guarantee neural changes.

For autonomy and self-determination, the companion should offer choices, explain recommendations, accept correction, and let users inspect, edit, export, or delete memory. Actions outside the app need separately configured permissions.

One architectural distinction: **offline mode can generate digests from downloaded or imported material; fresh news and opportunities require connectivity.**

Should the first deliverable be a **buildable Android app project**, or a **complete product specification and implementation prompt**?

You said:

Buildable android app project.

File

Baseline character bio is Jade. Here is their narrative lore and backstory.

ChatGPT said:

Download EngramDaily-Jade-Android.zip

Includes Jade's lore-grounded, editable engram; career profiles; daily digests and notifications; API and local GGUF inference; practice analytics; and scenario exercises.

Extract and open in Android Studio. The README includes build and signed-APK distribution instructions.

Validation: Java compilation, native syntax checks, and core tests passed. APK assembly and device testing remain unverified; model weights are imported separately.

Could we make a windows installer too?

Worked for 17m 56s >

You said:

Could we then make a localized, chatgpt specific version that has full calendar viability, taking data uploads from outlook and google, to enact all functionality in a self-contained chatgpt-centric prompt and notification system?

You said:

The .apk renders as a .zip file, not as an installable android file.

ChatGPT said:

The actual installers are ready:

- **Android:** Engram-Daily-Jade-0.1.0-test.apk
- **Windows:** Engram-Daily-Jade-Setup-0.1.0-x64.exe
- **ChatGPT prompt:** Jade-ChatGPT-Calendar.md

These are **test builds**. The APK signature verified; the Windows installer passed archive checks but is unsigned and hasn't been run on Windows.

Calendar imports work as snapshots. Live synchronization and ChatGPT notifications aren't activated. Scheduling still needs your delivery time and timezone.

The chat function does not appear to work. Could we also make sign in plug ins for the calendar function?
